Page Time Taken

Website developers can use this report to identify the pages that need the most optimization for CPU usage on the server.

Highly accessed pages that are very fast may have a higher score because of the number of hits. In this way, the report shows you the key pages that will have the most impact if optimized. For example, a page that is hit 10,000 times a day that takes 10ms to process causes much more load than a page that is hit 10 times that takes 1000ms to process.

To optimize the time taken on the page, optimize the code to reduce database calls, improve the page flow to reduce the work the server has to do, or implement caching.

Note: This report can be added as a report item to a custom report. For more information on report items, refer to [Understanding Report Items](#) .

For a definition of the terms listed on this page, please refer to the [Glossary](#) .
